Field of the Invention This invention relates to digital frequency synthesizers, and more particularly to a method of correcting the frequency produced by a digital frequency

synthesizer. 2. Description of the Prior Art A digital frequency synthesizer generates a frequency signal for output to an antenna.

For example, a radio transmitter that is controlled by a digital frequency synthesizer to output a RF signal for transmission. The digital frequency synthesizer determines the output frequency by performing a frequency comparison between a reference signal and a divided signal produced by a divide-by-N counter. The divided signal is compared to a frequency-to-voltage converter which produces a voltage that is proportional to the divided signal. The generated voltage is compared to a reference voltage to produce a digital value representative of the output frequency. The generated digital frequency value is then applied to a digital-to-frequency converter which produces the output frequency based upon the digital frequency value. The main source of error in a digital frequency synthesizer is the input frequency error which results from a $1/N$ error. In the example above, the $1/N$ error is produced when the divide-by-N counter produces a divided signal which is higher by $1/N$ than the reference signal. If the reference signal is equal to the divided signal, the $1/N$ error is a zero error. The $1/N$ error produces a frequency error in the digital value representative

of the output frequency which is also applied to
