It also explains the various front-ends (antennas) available for converting electrical energy to radio waves. Mathematically, a transmitter is an electrical circuit consisting of a current source, an inductor, a capacitor and a vacuum tube. Electrically, it is a transformer with a secondary current flowing through a resistor. The voltage difference between the primary side and the secondary side is transformed into radio waves by using two transformer winding methods. The first one relies on electro-magnetic induction where an alternating current generates a changing magnetic flux which induces a voltage across the primary winding of the transformer. The second one is an active antenna which relies on radio frequency circuits with vacuum tubes.
